ABSTRACT

Satellite Laser Ranging (SLR) offers the only unambiguous sub-centimeter range measurement to orbiting satellites. This capability finds many applications in addition to precision orbit determination (POD), which include a unique absolute measure of orbit accuracy, accurate altimeter range calibration, accurate definition of the Earth’s center of mass, the most accurate definition of the geocentric gravitational coefficient (GM) and scale of a terrestrial reference network. Achieving sub-centimeter precision requires appropriate modeling of the satellite laser retro-reflector array (LRA) coupled in some cases with appropriate modeling of the satellite-dependant station detector characteristics, a highly accurate terrestrial reference frame, and appropriate attention to possible bias modeling of individual stations. We have processed Jason1, Lageos1/2, and TOPEX SLR tracking using the latest and most accurate POD models which include a GRACE-based static gravity, time varying gravity, and the highly accurate ILRS update of the rescaled ITRF2005 SLR complement, SLRF2005. LPOD2005 has been again updated with subsequent recommendations for the rescaled ITRF2005, LPOD2005. Our analysis evaluates individual SLR station performance and systematic signals as observed from all four satellites. Several baseline stations are identified having significant biases, which if untreated could lead to degradation in current levels of POD accuracy, and possibly bias the results for other applications of the SLR measurement.

A priori SLR processing performance

The increase in SLR mean residuals indicates an increase in station bias or position error. This has a significant effect on the cm-level Jason-1 orbit. Much of the error has been removed using the LPOD2005 upgrade to SLRF2005, and a revised station bias strategy. Maintaining such orbit accuracy requires ongoing vigilant maintenance of a bias treatment plan for individual stations.

LPOD2005 solution

As shown below LPOD2005 improves station performance and reduces mean residuals over Jason-1 cycles 1-37.

SLR mean residuals for primary stations

The mean residual patterns shown below indicate the bias strategies for several primary stations may have to be revised. Trends suggest position velocity error.

Summary

- SLR processing now at the 1-cm level for Jason and Lageos, and 1.5-cm for Topex.
- At this level differentiating between station bias and position error is extremely difficult, but critical for further improvement.
- SLRF2005 offers a comprehensive station set, a significant improvement over the ITRF2005-SLR scaled station set.
- LPOD2005 significantly improves primary stations Emmenwaal, Riyadh, and Ajena.
- Hermes allows a 1.7 cm bias beginning about Feb 12, 2007, recent data from Wettzell, Herstmonceux shows a 1.2 cm bias beginning about Feb 12, 2007. Recent data from Wettzell, Herstmonceux shows a 1.2 cm bias beginning about Feb 12, 2007.
- Should POD standarts for the next ITF require a common bias strategy and atmosphere time-varying gravity modeling?
