## Introduction

### COMAPI: Coastal Modeling for Altimetry Product Improvement

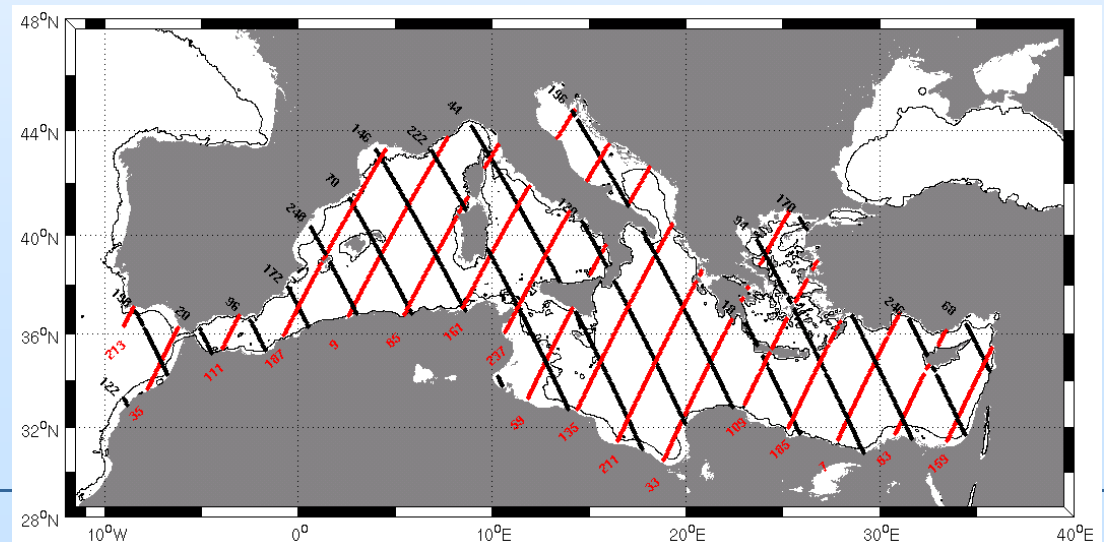

- **Global ocean models: not accurate enough to well represent the complex ocean dynamics and the high spatial variability of the process in the coastal zones**
- **Implementation of two regional dynamical atmospheric corrections for periods smaller than 20 days (high frequency) in:**
  - ◆ The North East Atlantic Ocean
  - ◆ The Mediterranean Sea
- **Development of two regional tide models with assimilation in the same zones**
  - ◆ Better atlases for the “classical” waves
  - ◆ Extension to some of the non-linear waves

# Regional high frequency DAC in the NEA Ocean and MED Sea

## Regional high frequency DAC in the North East Atlantic Ocean and in the Mediterranean Sea

Plots ©CTOH

## Regional high frequency DAC in the NEA Ocean and MED Sea

### ● Regional high frequency DAC: methodology

- ✦ TUGO 2D model (finite element model)
- ✦ Regional high resolution grids (NEA and MED)
- ✦ ECMWF 3h forcing fields
- ✦ Run period: Sept. 2008 - Dec. 2009

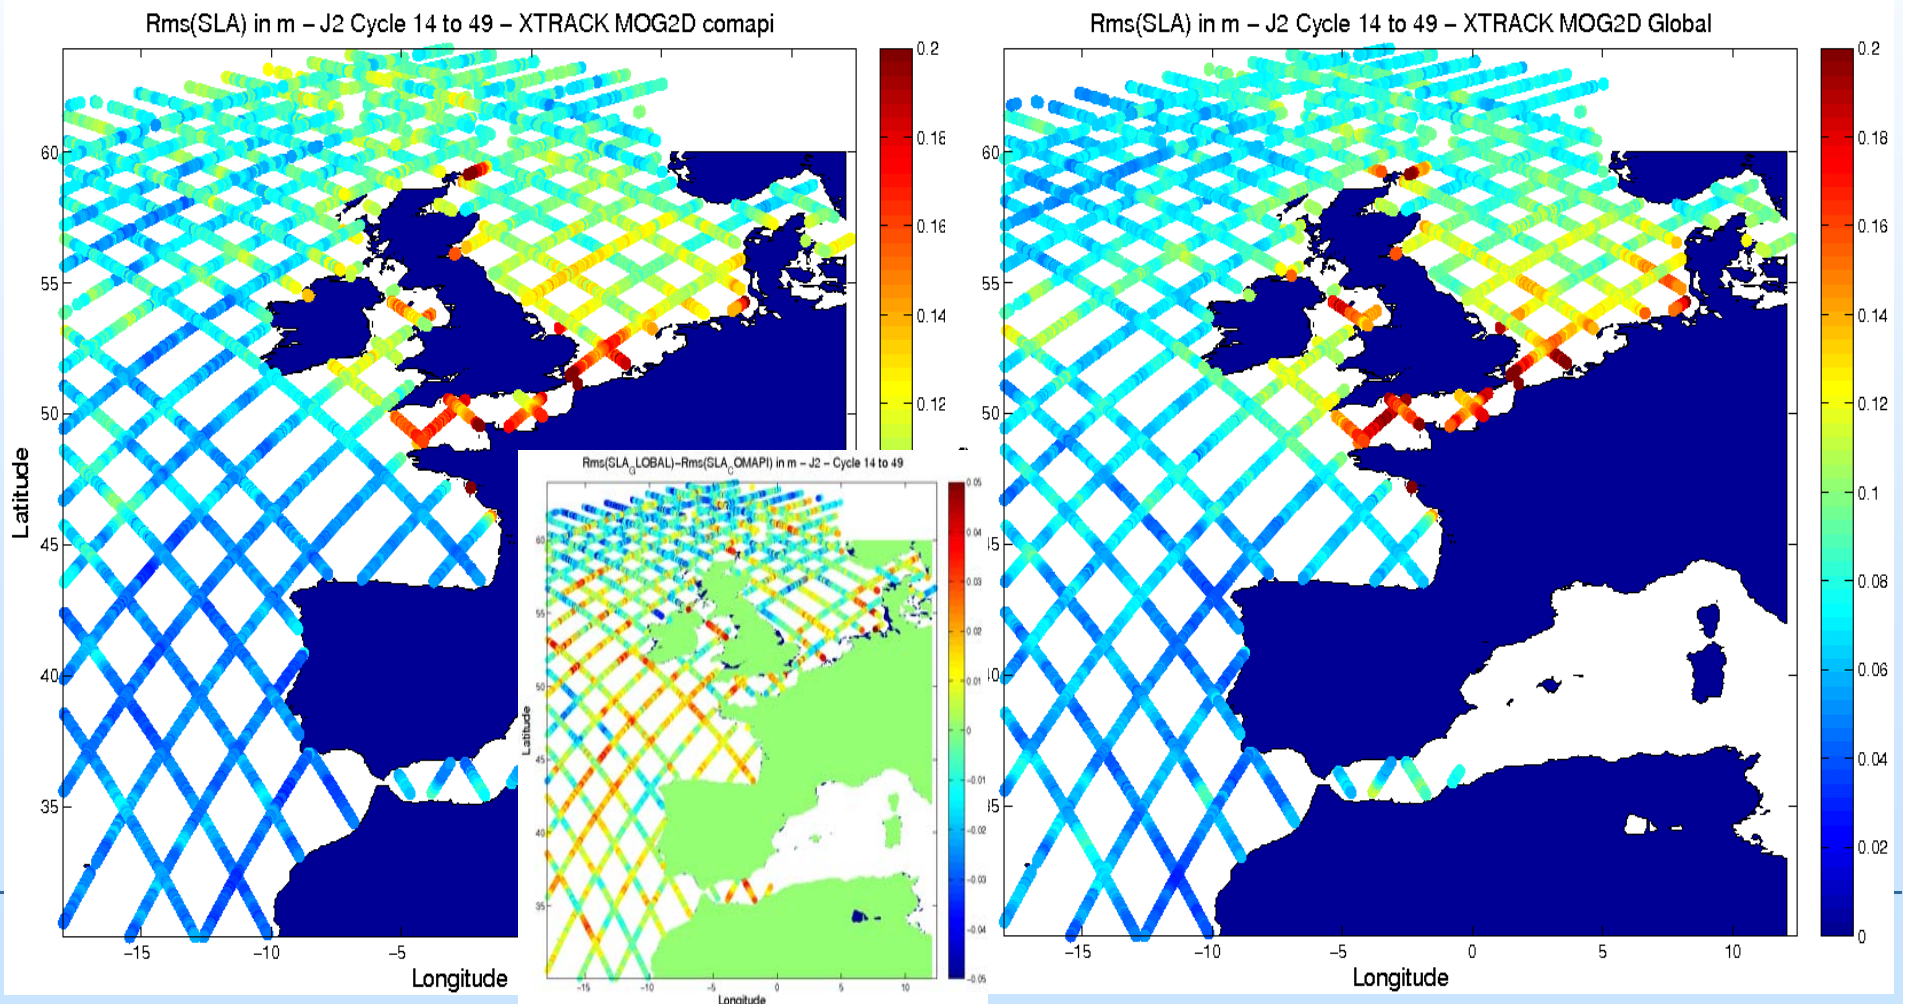

## Regional HF DAC: Validation method

- **Comparison to a tide gauge database (MATROOS)**
  
- **Evaluation of the impact in the altimetry data:**
  - ◆ **X-TRACK Jason-2 SLA provided by the CTOH (*see Birol et al presentation*)**
  
  - ◆ **Several dynamical atmospheric corrections:**
    - ★ COMAPI regional high frequency DAC (to be validated)
    - ★ TUGO global high frequency DAC (high resolution grid, ECMWF 6h forcing fields)
  
  - ◆ **Evaluation of the temporal variability reduction at each observation point**
    - **Regional picture of the new high frequency DAC impacts**

# Regional HF DAC: Validation in the NEA Ocean

## ● Impact on the Jason-2 SLA data provided by the CTOH

## Regional high frequency DAC: Validation in the MED Sea

### Comparison to the MATROOS tide gauge dataset: detided SLA

#### Global performance score

**On average, reduction of more than 62% of the tide gauge SLA variance when using the COMAPI simulation.**

## Conclusions on the HF DAC

### Conclusions

- ✦ **On-going validation work: preliminary results**
- ✦ **Choosing the most adapted ECMWF products to force the model is crucial.**

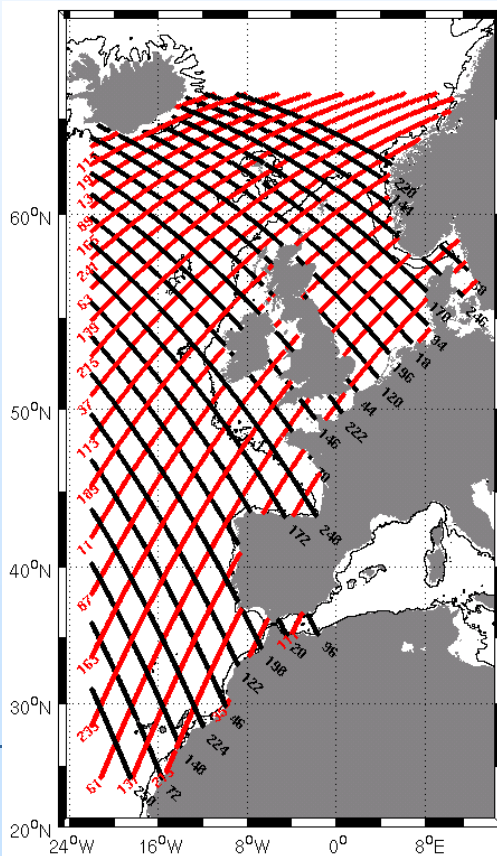

## Perspectives on the HF DAC

### Perspectives

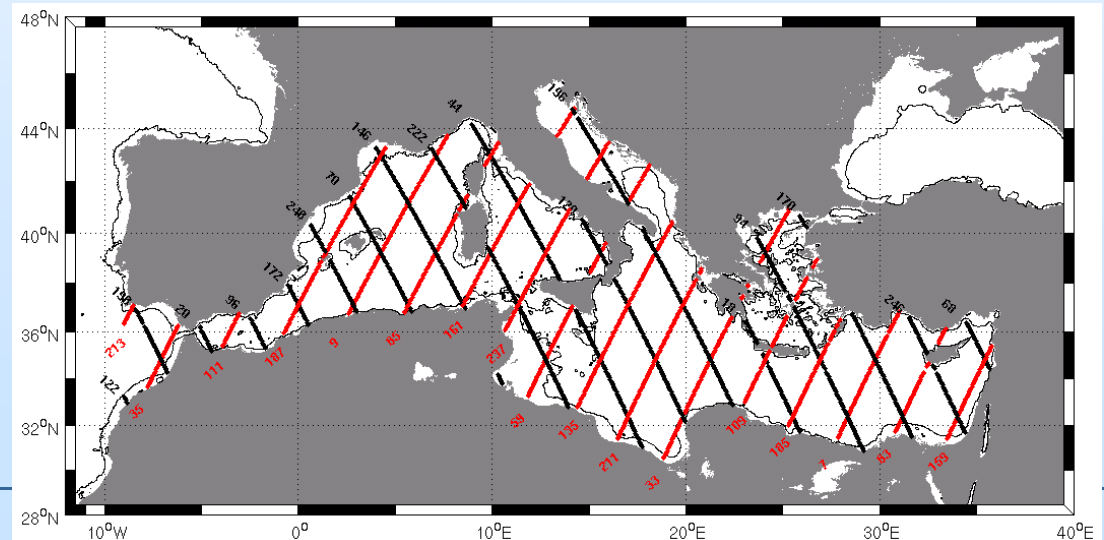

- ✦ Product intended to evaluate
- ✦ Increase the temporal resolution of the surface parameters: 1h atmospheric fields?
- ✦ Use regional atmospheric models to improve the forcings (MESO-NH, WRF)?

## Regional tide atlases in the NEA and MED

# Regional tide atlases in the North East Atlantic Ocean and in the Mediterranean Sea

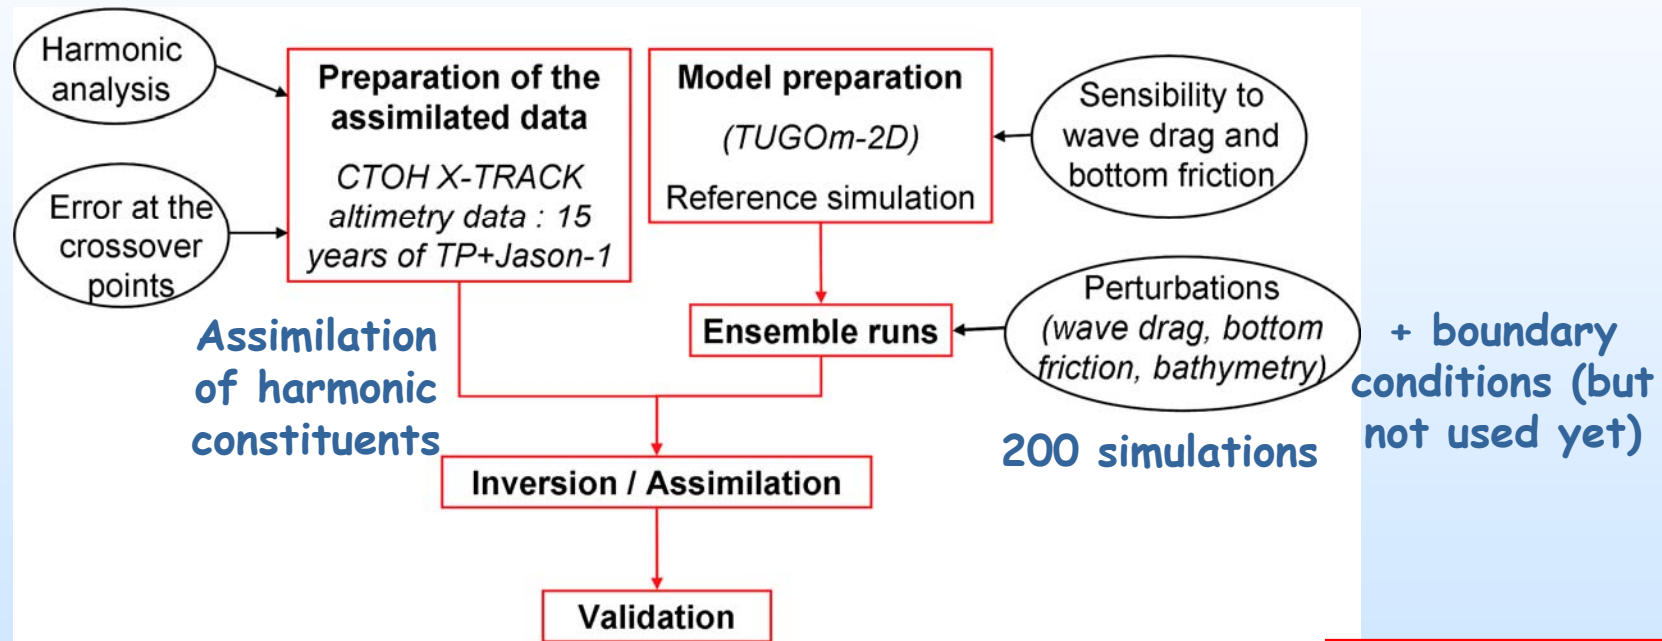

Plots ©CTOH

## Regional tide atlases in the NEA and MED

### Regional tide models development: methodology

**NEA: assimilation of altimetry data + coastal tide gauges**

**47-wave spectrum**

**MED: assimilation of altimetry data**

**15 assimilated waves**

**For each zone : 1 reference solution (no assim) + 1 assimilated solution**

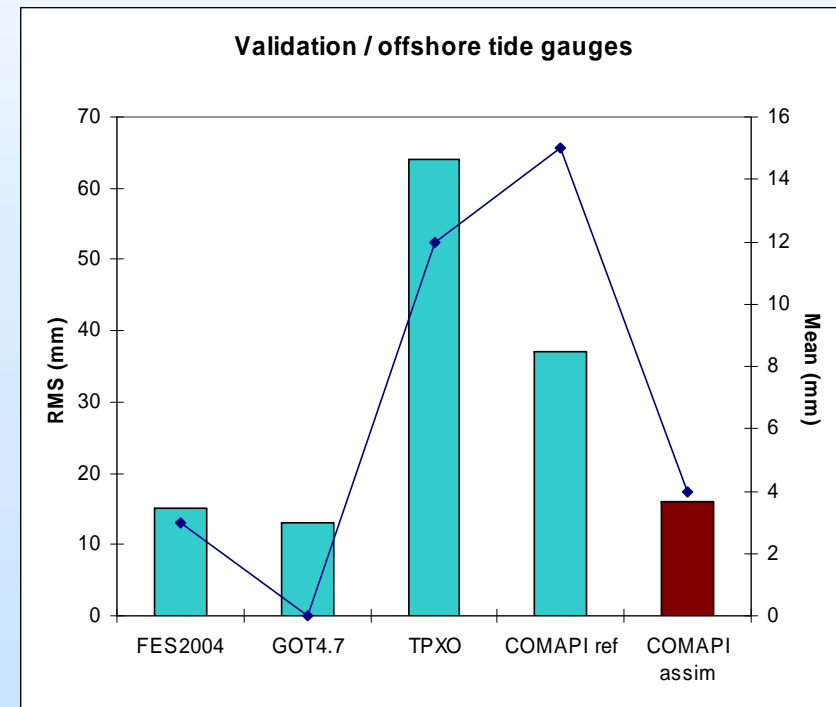

## Regional tide atlases: Validation method

- **Comparison to tide gauge datasets, wave by wave**
  
  - **Evaluation of the impact in the altimetry data, compared to other tide models :**
    - ◆ **X-TRACK Jason-1 SLA provided by the CTOH**
    - ◆ **Several tide corrections:**
      - ★ FES2004
      - ★ GOT4.7
      - ★ COMAPI reference solution (no assimilation)
      - ★ COMAPI assimilated solution (to be validated)
    - ◆ **Evaluation of the temporal variability reduction at each observation point**
- Regional picture of the new tide solution impacts**

## Regional tide atlases: Validation in the NEA

### Comparison to tide gauge datasets (wave by wave)

- ◆ Global performance score: vector differences for M2
- ◆ Comparison to global models (FES2004, GOT4.7, TPXO7.2)

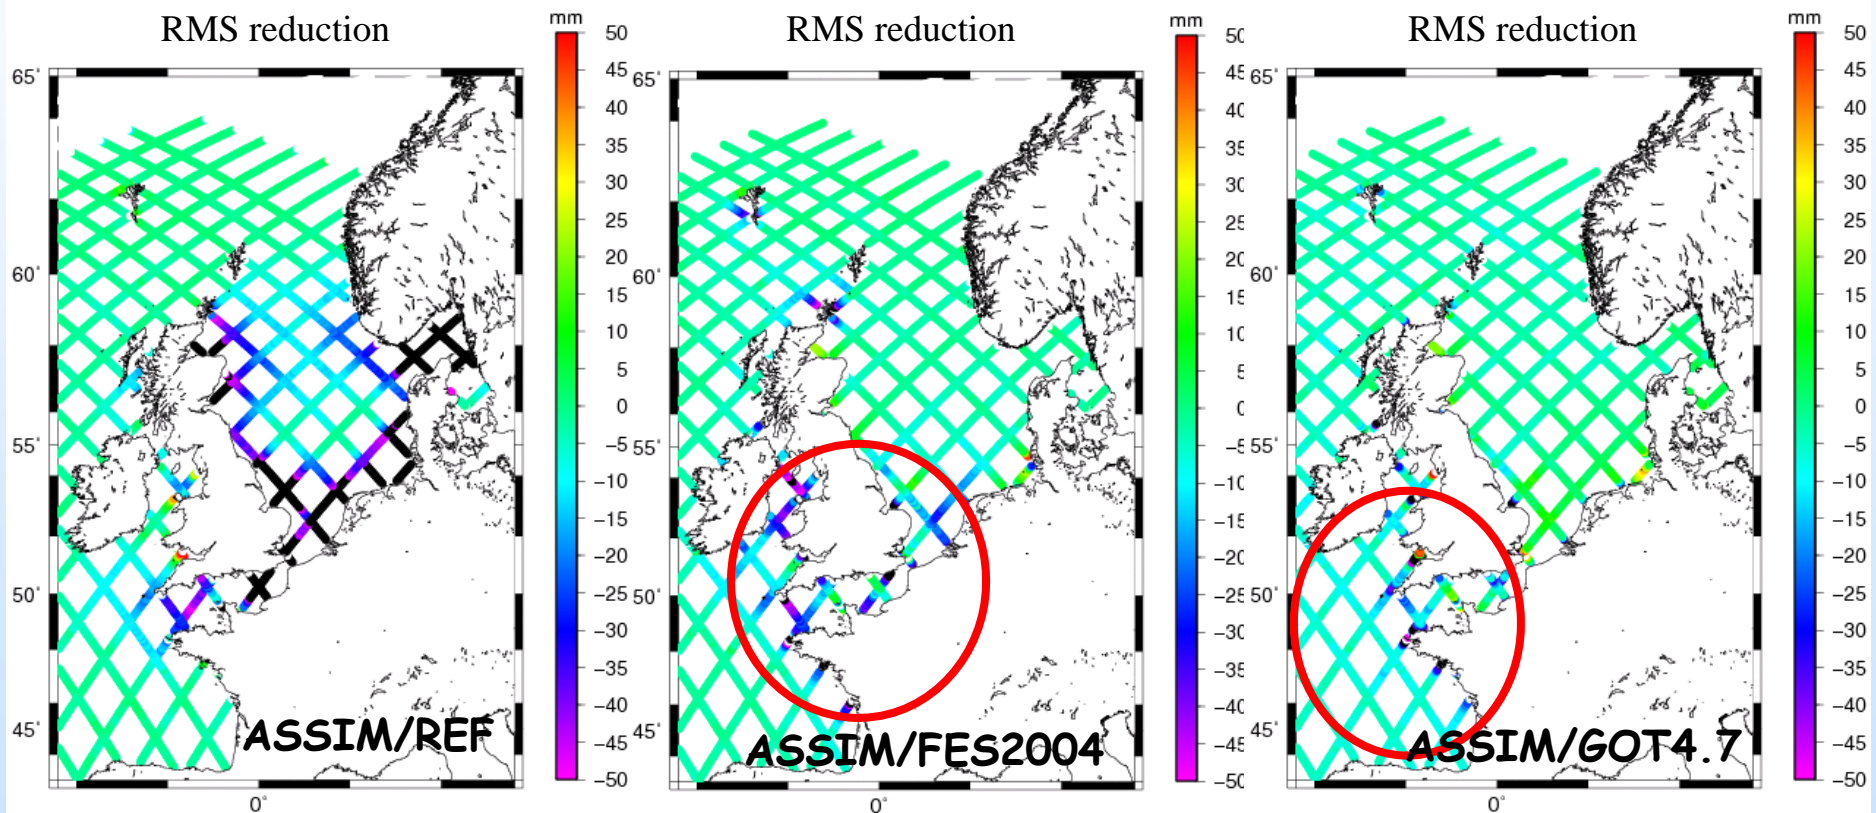

## Regional tide atlases: Validation in the NEA

- **Comparison to tide gauge datasets (wave by wave)**
  - ✦ **Global performance score: vector differences for M2**
  - ✦ **Comparison to global models (FES2004, GOT4.7, TPXO7.2)**

- **Better scores with coastal tide gauges than with offshore ones**
- **Coastal tide gauges were assimilated, but same conclusion with a solution containing only altimetry data**
  - ➔ **The altimetry data highly constrain the model.**

# Regional tide atlases: Validation in the NEA

## ● Impact on the Jason-1 SLA data provided by the CTOH

## Regional tide atlases: Validation in the NEA

**OFFSHORE:** Better scores with the altimeter data than with the tide gauge ones.

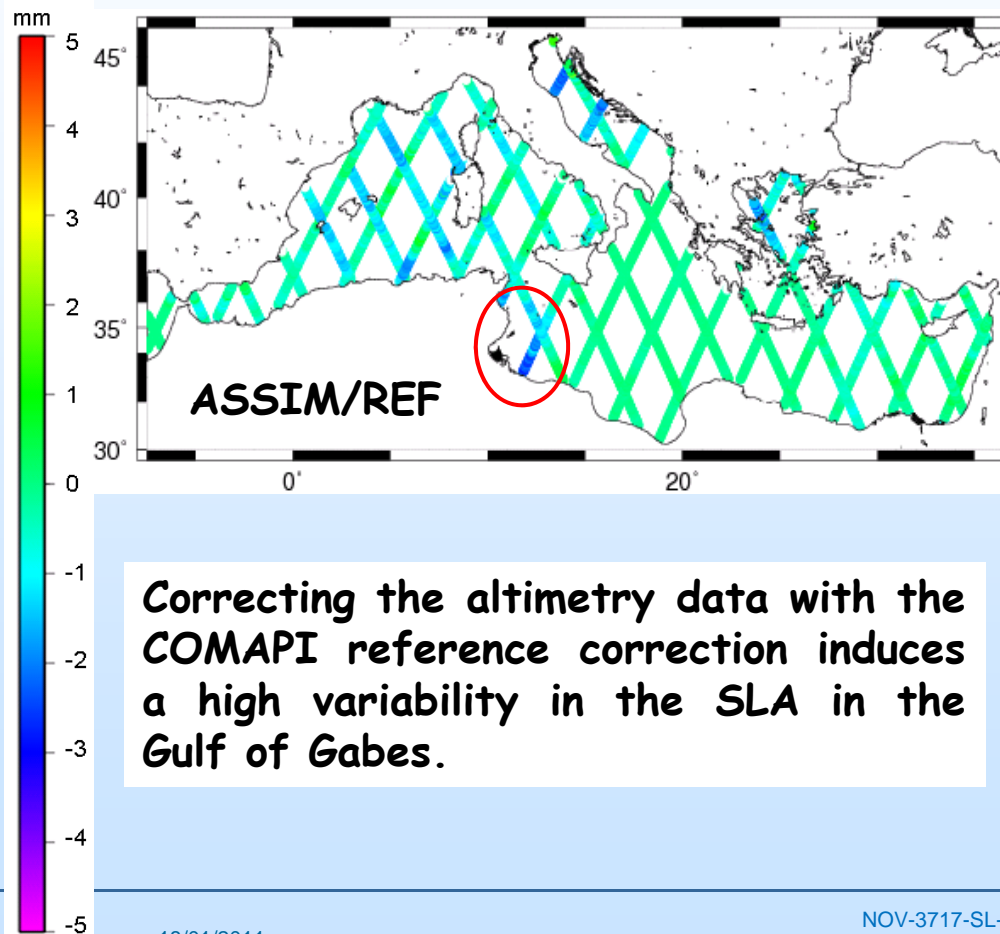

It may be due to the **load tide** as:

- Assimilated altimetry data were corrected from the global FES99 load tide (1/4° spatial resolution for the load tide)
- Load tide highly variable near the coasts: not well represented in the FES99 model.
- It induces some errors in the assimilated data and thus in the assimilated solution.
- This error vanishes when computing the geocentric tide
  - ➔ no impact in the altimetry data as far as the same load tide correction is used
- On the contrary, impacts the oceanic tide and degrades the comparison to the tide gauge harmonic constituents.

**An iteration to compute a load tide homogeneous with the COMAPI tide atlas would probably improve the results.**

## Regional tide atlases: Validation in the Mediterranean Sea

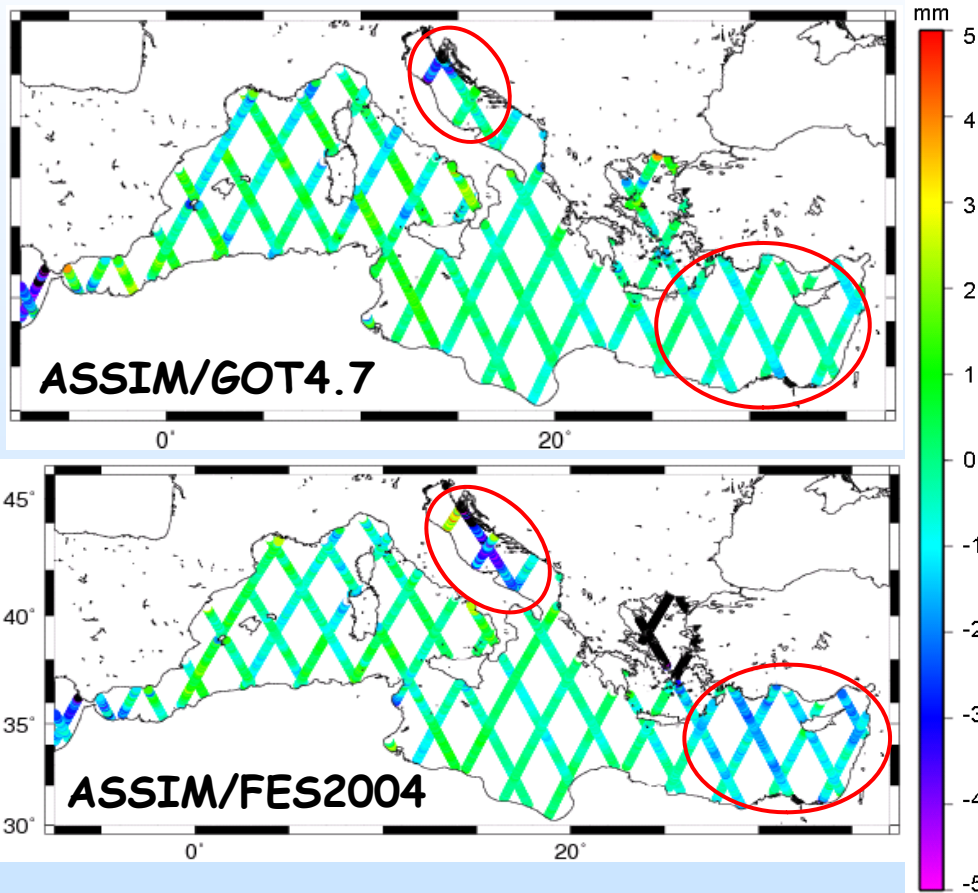

### ● Impact on the Jason-1 SLA data provided by the CTOH

- Probably due to a local bathymetry default
- The model bathymetry ensembles do not take this issue into account
- It induces non pertinent model error covariances which propagate in a large part of the basin
- To disconnect this zone from the others: limitation of the influence radius of the assimilated observations
- ➔ The assimilation of altimetry data corrects this anomaly
- ➔ A high quality bathymetry is crucial when modeling the tides

## Regional tide atlases: Validation in the Mediterranean Sea

### ● Impact on the Jason-1 SLA data provided by the CTOH

**Reduction of the variability compared to the global models especially:**

→ In the Levantine basin

→ In the Adriatic Sea

## Conclusions on the tide atlases

### Conclusions

#### ◆ Improvement of the tide atlases near the coasts:

- ★ Decrease in the RMS of the altimetry SLA between 0.5cm and 5cm in the Channel and off Brittany, compared to GOT4.7 and the COMAPI reference solution (no assimilation)
- ★ Good coherency with the tide gauge harmonic constituents especially near the coasts
- ★ Offshore, better results with the altimetry data than with the tide gauges **probably because of the load tide.**

#### ◆ Necessity to compute an homogeneous load tide

#### ◆ The definition of the bathymetry ensembles must be done carefully, maybe in two steps:

- 1) partitioning the zone a priori → identification of bathymetry defaults
- 2) new zoning to improve the assimilation

## Conclusions on the tide atlases

### Perspectives

#### ◆ These regional tide atlases will be patched in global models

*Today*

- ★ Boundary conditions ensembles were not used in the simulation  
→ can immediately be patched in FES2004

*Next step*

- ★ There are still errors in the boundary conditions: the boundary conditions ensembles will be used in the ensembles runs
- ★ Use of the boundary conditions to create a "buffer zone" between the global and the regional atlases.  
→ patch the regional model in any global one.

## General conclusions and perspectives

### ● General conclusions

- ◆ Both validated products will be included in the PISTACH altimetry products
- ◆ The production of the atlases showed:
  - ★ Need for reliable bathymetry fields
  - ★ Necessity to compute load tides homogeneous with the regional tide atlases

# General conclusions and perspectives

## ● Perspectives

### ◆ Next priorities ?

- ★ Artic Ocean
- ★ Indian Ocean
- ★ African coasts
- ★ Indonesian straits
- ★ Gulf of Mexico
- ★ Amazon shelf
- ★ ... other suggestions ?

### ◆ Bathymetry ?

### ◆ Regional altimetry datasets production ?

### ◆ Tide gauge time series availability ?
